

Light propagation in electrically driven liquid-core/liquid-cladding optical waveguides with electromicrofluidics

Liquid-core/liquid-cladding optical waveguides offer optically smooth liquid/liquid interfaces to guide light along microfluidic liquid streams with adjustable optical properties. We investigated dielectrophoresis (DEP) on an electromicrofluidic platform to construct reconfigurable liquid-core/liquid-cladding optical waveguides by applying adequate electric fields between parallel plates without the constant liquid supply usually needed for laminar flow in physical microchannels. L-shaped, spiral, and straight stationary waveguides were prepared to investigate light guiding and propagation, whereas moving waveguides were established to perform light switching.

As shown in Figure 1, liquid optical waveguide cores were driven on an electromicrofluidic platform between two parallel plates without physical channel walls. With a sufficient nonuniform electric field, DEP generated surface forces to continuously deform and pump the higher-permittivity liquid (core liquid) along the strong electric field into the region containing the lower-permittivity medium (cladding liquid). Because the core liquid was defined by the electric field instead of by laminar flow along physical microchannels, waveguides with arbitrary two-dimensional shapes were obtained by applying a voltage to appropriately designed electrode patterns on the plates. After forming the waveguide,

light was coupled to it.

The core liquid, γ -butyrolactone (GBL, $C_4H_6O_2$, $n_{\text{core}} = 1.4341$, $\epsilon_{\text{core}} = 39$), was tested and manipulated with DEP in silicone oil ($n_{\text{cladding}} = 1.401$, $\epsilon_{\text{cladding}} = 2.5$) as the cladding liquid by applying a voltage to Teflon-coated ITO (indium tin oxide) electrodes on the inner surfaces of two parallel glass plates. In the stationary L-shaped waveguide, light was guided into the GBL virtual micro-channel core for a total of 27.85 mm via a 90° bend (radius 5 mm) before exiting the light outlet with a cross-sectional area of $100 \mu\text{m} \times 100 \mu\text{m}$. For the stationary spiral waveguide (cross-sectional area of $100 \mu\text{m} \times 100 \mu\text{m}$), light was guided into the GBL core

containing rhodamine 6G (R6G, 1 mM) dye through a series of 90° bends with radii decreasing from 5 mm to 2.5 mm. In the stationary straight waveguide (height 100 μm , width 150 μm), the propagation loss was measured to be 2.09 dB/cm in the GBL with R6G (0.01 mM). To implement the moving L-shaped waveguide, electrowetting and DEP generated a precise GBL droplet and then formed a waveguide core on the electromicrofluidic platform. Upon sequentially applying the appropriate voltage to each of three parallel L-shaped driving electrodes, the GBL waveguide core shifted; the guided light

was switched to a speed of up to 0.929 mm/s (switching period 70 ms, switching rate 14.3 Hz) when an adequate electric signal (173.1 V_{RMS} , 100 kHz) was applied.

The DEP-defined waveguide demonstrated simple fabrication, flexible optical and fluidic pathways, and static core/cladding liquids without flow disturbances. The demonstrated liquid-core/liquid-cladding optical waveguides are ready to be integrated with other microfluidic functionalities and optofluidic components on a single electromicrofluidic platform.

A fast-track characterization protocol of spin-orbit torque efficiencies

Spin-orbit coupling is a source of many exotic physical phenomena found in various condensed matter systems; these phenomena, such as the current-induced spin Hall effect (SHE) and the spin-orbit torque (SOT), originate from transition metal-based and emergent material-based magnetic heterostructures. The SHE-induced SOT and its related effects have been widely studied both theoretically and experimentally and demonstrated by harnessing the magnetization dynamics in certain material systems (e.g., Pt-, Ta-, and W-based heterostructures). Therefore, the SOT effect might become a major mechanism for controlling next-generation spintronic devices, such as magnetic random access memory (MRAM)/SOT-
